

# String Data Type and Operations

Hui Chen

Department of Computer & Information Science

Brooklyn College

# Objectives

- To introduce objects and instance methods (§4.4).
- To represent strings using the **String** objects (§4.4).
- To return the string length using the **length()** method (§4.4.1).
- To return a character in the string using the **charAt(i)** method (§4.4.2).
- To use the **+** operator to concatenate strings (§4.4.3).
- To read strings from the console (§4.4.4).
- To read a character from the console (§4.4.5).
- To compare strings using the **equals** method and the **compareTo** methods (§4.4.6).
- To obtain substrings (§4.4.7).
- To find a character or a substring in a string using the **indexOf** method (§4.4.8).

# Outline

- Discussed
  - The char data type and The Character class
- The String data type
  - String class, objects, and invoking the instance methods
  - Simple (important) methods and operations of String objects
    - Getting the length, getting a character
    - Concatenating strings
    - Reading strings, characters from the console
    - Comparing strings using the equals and compareTo methods
    - Obtaining substrings
    - Finding a character or a substring

# The String Data Type

- The char type only represents one character. To represent a string of characters, use the data type called String.
- Example
  - `String message = "Welcome to Java";`

# The String Class

- String is actually a predefined class in the Java library just like the System class and Scanner class.
- The String type is not a primitive type. It is known as a *reference type*.
- Any Java class can be used as a reference type for a variable.
- For the time being, you just need to know
  - how to declare a String variable,
  - how to assign a string to the variable,
  - how to concatenate strings, and
  - how to perform simple operations for strings.

# Simple Methods for **String** Objects

| <b>Method</b>              | <b>Description</b>   |
|----------------------------|--|
| <code>length()</code>      | Returns the number of characters in this string.                                 |
| <code>charAt(index)</code> | Returns the character at the specified index from this string.                   |
| <code>concat(s1)</code>    | Returns a new string that concatenates this string with string <code>s1</code> . |
| <code>toUpperCase()</code> | Returns a new string with all letters in uppercase.                              |
| <code>toLowerCase()</code> | Returns a new string with all letters in lowercase.                              |
| <code>trim()</code>        | Returns a new string with whitespace characters trimmed on both sides.           |

# Remark: Simple Methods for **String** Objects

- Strings are **objects** in Java.
- The methods in the preceding table can only be invoked from a specific string object/instance.
- For this reason, these methods are called *instance methods*.
- A non-instance method is called a *static method*.
- A static method can be invoked without using an object.
- All the methods defined in the **Math** class are static methods.
- They are not tied to a specific object instance. The syntax to invoke an instance method is
  - **referenceVariable.methodName(arguments)**

# Getting String Length

```
String message = "Welcome to Java";
```

```
System.out.println("The length of " + message + " is  
" + message.length());
```

# Getting Characters from a String

```
String message = "Welcome to Java";  
System.out.println("The first character in  
message is "  
+ message.charAt(0));
```

# Converting Strings

- Examples

"Welcome".toLowerCase() returns a new string, welcome.

"Welcome".toUpperCase() returns a new string,  
WELCOME.

" Welcome ".trim() returns a new string, Welcome.

# String Concatenation

- Examples

```
String s3 = s1.concat(s2); or String s3 = s1 + s2;
```

```
// Three strings are concatenated
```

```
String message = "Welcome " + "to " + "Java";
```

```
// String Chapter is concatenated with number 2
```

```
String s = "Chapter" + 2; // s becomes Chapter2
```

```
// String Supplement is concatenated with character B
```

```
String s1 = "Supplement" + 'B'; // s1 becomes SupplementB
```

# Reading Strings from the Console

- Examples

```
Scanner input = new Scanner(System.in);
```

```
System.out.print("Enter three words separated by spaces: ");
```

```
String s1 = input.next();
```

```
String s2 = input.next();
```

```
String s3 = input.next();
```

```
System.out.println("s1 is " + s1);
```

```
System.out.println("s2 is " + s2);
```

```
System.out.println("s3 is " + s3);
```

# Reading a Character from the Console

- Examples

```
Scanner input = new Scanner(System.in);
```

```
System.out.print("Enter a character: ");
```

```
String s = input.nextLine();
```

```
char ch = s.charAt(0);
```

```
System.out.println("The character entered is " + ch);
```

# Compare Strings

| <b>Method</b>                        | <b>Description</b>  |
|--------------------------------------|---|
| <code>equals(s1)</code>              | Returns true if this string is equal to string <code>s1</code> .  |
| <code>equalsIgnoreCase(s1)</code>    | Returns true if this string is equal to string <code>s1</code> ; it is case insensitive.  |
| <code>compareTo(s1)</code>           | Returns an integer greater than 0, equal to 0, or less than 0 to indicate whether this string is greater than, equal to, or less than <code>s1</code> . |
| <code>compareToIgnoreCase(s1)</code> | Same as <code>compareTo</code> except that the comparison is case insensitive.  |
| <code>startsWith(prefix)</code>      | Returns true if this string starts with the specified prefix.   |
| <code>endsWith(suffix)</code>        | Returns true if this string ends with the specified suffix.   |

# Obtaining Substrings

| Method                                       | Description   |
|--|---|
| <code>substring(beginIndex)</code>           | Returns this string's substring that begins with the character at the specified <code>beginIndex</code> and extends to the end of the string, as shown in Figure 4.2.   |
| <code>substring(beginIndex, endIndex)</code> | Returns this string's substring that begins at the specified <code>beginIndex</code> and extends to the character at index <code>endIndex - 1</code> , as shown in Figure 9.6. Note that the character at <code>endIndex</code> is not part of the substring. |

# Finding a Character or a Substring

| Method                                  | Description  |
|---|--|
| <code>indexOf(ch)</code>                | Returns the index of the first occurrence of <code>ch</code> in the string. Returns <code>-1</code> if not matched.                                      |
| <code>indexOf(ch, fromIndex)</code>     | Returns the index of the first occurrence of <code>ch</code> after <code>fromIndex</code> in the string. Returns <code>-1</code> if not matched.         |
| <code>indexOf(s)</code>                 | Returns the index of the first occurrence of string <code>s</code> in this string. Returns <code>-1</code> if not matched.                               |
| <code>indexOf(s, fromIndex)</code>      | Returns the index of the first occurrence of string <code>s</code> in this string after <code>fromIndex</code> . Returns <code>-1</code> if not matched. |
| <code>lastIndexOf(ch)</code>            | Returns the index of the last occurrence of <code>ch</code> in the string. Returns <code>-1</code> if not matched.                                       |
| <code>lastIndexOf(ch, fromIndex)</code> | Returns the index of the last occurrence of <code>ch</code> before <code>fromIndex</code> in this string. Returns <code>-1</code> if not matched.        |
| <code>lastIndexOf(s)</code>             | Returns the index of the last occurrence of string <code>s</code> . Returns <code>-1</code> if not matched.  |
| <code>lastIndexOf(s, fromIndex)</code>  | Returns the index of the last occurrence of string <code>s</code> before <code>fromIndex</code> . Returns <code>-1</code> if not matched.                |

# Examples of Finding Characters and Substrings

```
int k = s.indexOf(' ');
```

```
String firstName = s.substring(0, k);
```

```
String lastName = s.substring(k + 1);
```

# Conversion between Strings and Numbers

- Examples

```
int intValue = Integer.parseInt(intString);
```

```
double doubleValue = Double.parseDouble(doubleString);
```

```
String s = number + "";
```
