Distance Vector

- Each node constructs a one dimensional array (a vector) containing the "distances" (costs) to all other nodes and distributes that vector to its immediate neighbors
- Starting assumption is that each node knows the cost of the link to each of its directly connected neighbors

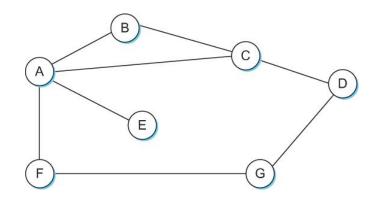

Distance From a Node to Other Nodes

- ☐ What is the (shortest) distance from A to B?
- What is the (shortest) distance from A to C?
- ☐ What is the (shortest) distance from A to D?

Distance Vector: Example of Initial Routing Table

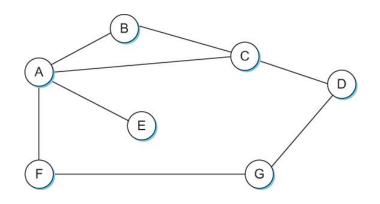

Initial routing table at node A

Destination	Cost	NextHop
В	1	В
С	1	С
D	∞	_
E	1	Е
F	1	F
G	∞	_

Distance Vector: Example of Final Routing Table

Final routing table at node A

	\ \ \ \ \ \			
Destination	Cost	NextHop		
В	1	В		
С	1	C		
D	2	С		
E	1	/ E		
F	1	/ F		
G	2	F		

Distance vector: distances from A

to the other nodes

Exercise

• Given an internetwork below, construct the *initial* routing table for the distance vector routing algorithm at *router C* (by filling the provided table below)

	Destination	Cost	Next Hop
	A		
	В		
)	D		
	E		
	F		
	G		

Distance Vector Routing Algorithm

Main idea

 Every T seconds each router sends its table to its neighbor each router then updates its table based on the new information

Problems

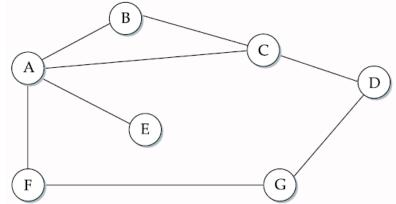

- Fast response to good news, but slow response to bad news
- Also too many messages to update

Distance Vector Routing Algorithm: More Details

- Each node maintains a routing table consisting of a set of triples
 - (Destination, Cost, NextHop)
- Exchange updates directly connected neighbors
 - periodically (on the order of several seconds)
 - whenever table changes (called triggered update)
- Each update is a list of pairs:
 - (Destination, Cost): from sending router to destination
 - Update local table if receive a "better" route
 - smaller cost
 - came from next-hop
- Refresh existing routes; delete if they time out

Table Update

Example: Exchange updates between A and C

☐ Then A sends an update to C

Destination	Cost
В	1
С	1
D	∞
Е	1
F	1
G	∞

C's initial routing table

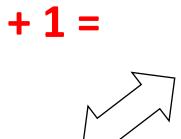

Destination	Cost	Next Hop
А	1	А
В	1	В
D	1	D
Е	∞	-
F	∞	-
G	∞	-

C's updated routing table

Destination	Cost	Next Hop
Α	1	А
В	1	В
D	1	D
E	2	Α
F	2	Α
G	∞	-

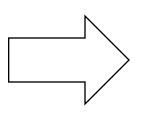

Table Update from A at C

Destination	Cost
В	1
С	1
D	∞
E	1
F	1
G	∞

Destination	Cost	Next Hop
Α	1	A
В	1	В
D	1	D
Е	8	-
F	∞	-
G	∞	-

Destination	Cost	Next Hop
В	2	Α
С	2	А
D	∞	Α
E	2	Α
F	2	А
G	∞	Α

Destination	Cost	Next Hop
Α	1	А
В	1	В
D	1	D
Е	2	Α
F	2	Α
G	∞	-

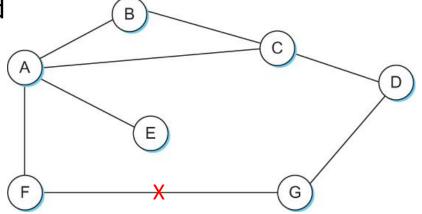

Convergence

- Process of getting consistent routing information to all the nodes
- Desired results: routing tables converges to a stable global table (no more changes upon receiving updates from neighbors)

Information	Distance to Reach Node						
Stored at Node	Α	В	С	D	Е	F	G
A	0	1	1	2	1	1	2
В	1	0	1	2	2	2	3
С	1	1	0	1	2	2	2
D	2	2	1	0	3	2	1
E	1	2	2	3	0	2	3
F	1	2	2	2	2	0	1
G	2	3	2	1	3	1	0

Link Failure: Example

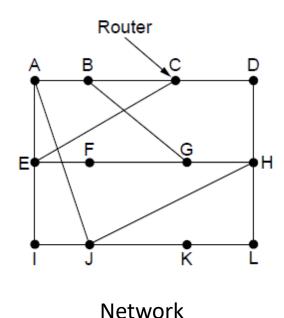

- When a node detects a link failure
 - F detects that link to G has failed
 - F sets distance to G to infinity and sends update to A
 - A sets distance to G to infinity since it uses F to reach G
 - A receives periodic update from C with 2-hop path to G
 - A sets distance to G to 3 and
 - F decides it can reach G in 4 (A)

Count-to-infinity Problem

- Slightly different circumstances can prevent the network from stabilizing
 - Suppose the link from A to E goes down
 - In the next round of updates, A advertises a distance of infinity to E, but B and C advertise a distance of 2 to E
 - Depending on the exact timing of events, the following might happen
 - Node B, upon hearing that E can be reached in 2 hops from C, concludes that it can reach E in 3 hops and advertises this to A
 - Node A concludes that it can reach E in 4 hops and advertises this to C
 - Node C concludes that it can reach E in 5 hops; and so on.
 - This cycle stops only when the distances reach some number that is large enough to be considered infinite
 - called count-to-infinity problem

Distance Vector: Example

delay from J To A Н Κ Line Α Н Ε G Н Н K Κ JK JA JH delay delay delay delay New vector is is is is for J

New estimated

Vectors received at J from Neighbors A, I, H and K

Count-to-Infinity Problem: Example

Failures can cause DV to "count to infinity" while seeking a path to an

Α	В	С	D	E
•	•	•	•	Initially
	1	•	•	After 1 exchange
	1	2	•	 After 2 exchanges
	1	2	3	 After 3 exchanges
	1	2	3	4 After 4 exchanges
	1	2		After 3 exchanges

Good news of a path to A spreads quickly

A	В	С	D	E	
•	1	2	3	4	Initially
	3	2	3	4	After 1 exchange
	3	4	3	4	After 2 exchanges
	5	4	5	4	After 3 exchanges
	5	6	5	6	After 4 exchanges
	7	6	7	6	After 5 exchanges
	7	8	7	8	After 6 exchanges
		:			
	•	•	•	•	

Bad news of no path to A is learned slowly

Count-to-infinity Problem: Solutions

- Use some relatively small number as an approximation of infinity
- For example, the maximum number of hops to get across a certain network is never going to be more than 16
 - Set infinity to 16
 - Stabilize fast, but not working for larger networks
- One technique to improve the time to stabilize routing is called split horizon

Split Horizon

- When a node sends a routing update to its neighbors, it does not send those routes it learned from each neighbor back to that neighbor
- For example, if B has the route (E, 2, A) in its table, then it knows it must have learned this route from A, and so whenever B sends a routing update to A, it does not include the route (E, 2) in that update

Split Horizon with Poison Reverse

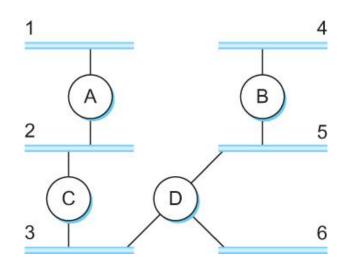

- In a stronger version of split horizon,
 called split horizon with poison reverse
 - B actually sends that back route to A, but it puts negative information in the route to ensure that A will not eventually use B to get to E
 - For example, B sends the route (E, ∞) to

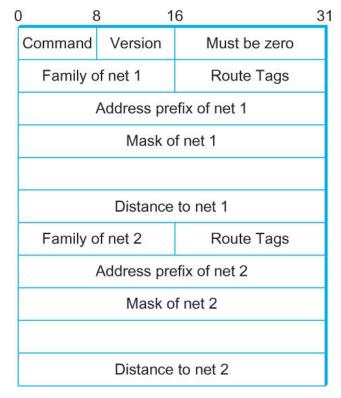

Routing Information Protocol

- Routing Information Protocol (RIP)
 - Initially distributed along with BSD Unix
 - Widely used
- Straightforward implementation of distance-vector routing

Routing Information Protocol (RIP)

- Distance: cost (# of routers) of reach a network
 - $\cdot C \rightarrow A$
 - Network 2 at cost 0; 3 at cost 0
 - Network 5 at cost 1, 4 at 2

Example Network

RIPv2 Packet Format

Questions?

- Shortest path problem and algorithm
- Distance Vector Routing
 - Problems with distance vector routing?
- Implementation of Distance Vector Routing
 - Routing information protocol

Link State Routing

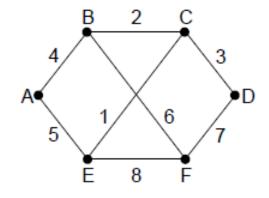

- Link state is an alternative to distance vector
 - More computation but simpler dynamics
 - Widely used in the Internet (OSPF, ISIS)
- Algorithm:
 - Each node floods information about its neighbors in LSPs (Link State Packets); all nodes learn the full network graph
 - Each node runs Dijkstra's algorithm to compute the path to take for each destination

Link State Routing

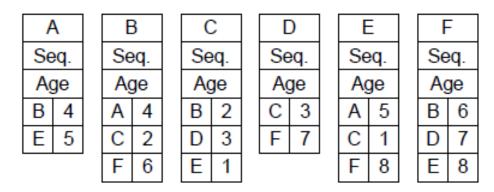

- Strategy: Send to all nodes (not just neighbors) information about directly connected links (not entire routing table).
- Link State Packet (LSP)
 - id of the node that created the LSP
 - cost of link to each directly connected neighbor
 - sequence number (SEQNO)
 - time-to-live (TTL) for this packet
- Reliable Flooding
 - store most recent LSP from each node
 - forward LSP to all nodes but one that sent it
 - generate new LSP periodically; increment SEQNO
 - start SEQNO at 0 when reboot
 - decrement TTL of each stored LSP; discard when TTL=0

Link State Packet: Example

LSP (Link State Packet) for a node lists neighbors and weights of links to reach them

Network

LSP for each node

Reliable Flooding

- Reliable flooding triggered by
 - Timer
 - Topology or link cost change
- increment SEQNO
 - start SEQNO at 0 when reboot
 - SEQNO does not wrap
 - e.g., 64 bits
 - decrement TTL of each stored LSP
- discard when TTL=0

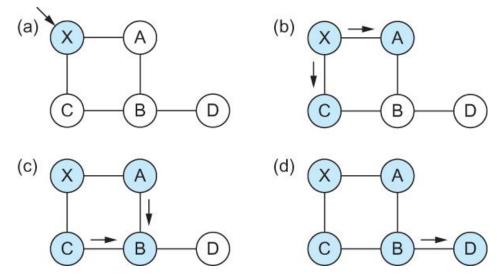

Reliable Flooding: Example

- Seq. number and age are used for reliable flooding
 - New LSPs are acknowledged on the lines they are received and sent on all other lines
 - Example shows the LSP database at router B

			Send flags		ACK flags		gs		
Source	Seq.	Age	Á	С	È	Á	С	È	Data
Α	21	60	0	1	1	1	0	0	
F	21	60	1	1	0	0	0	1	
E	21	59	0	1	0	1	0	1	
С	20	60	1	0	1	0	1	0	
D	21	59	1	0	0	0	1	1	

Reliable Flooding: Example

Reliable Flooding

Flooding of link-state packets. (a) LSP arrives at node X; (b) X floods LSP to A and C; (c) A and C flood LSP to B (but not X); (d) flooding is complete

Shortest Path Routing Algorithm

- In practice, each switch computes its routing table directly from the LSPs it has collected using a realization of Dijkstra's algorithm called the forward search algorithm
- Specifically each switch maintains two lists, known as **Tentative** and **Confirmed**
- Each of these lists contains a set of entries of the form (Destination, Cost, NextHop)

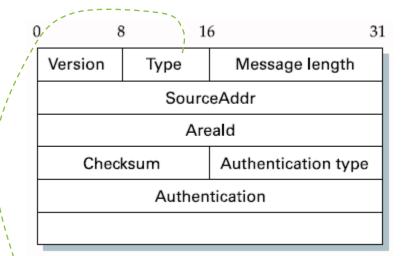

Link State in Practice

- Open Shortest Path First Protocol (OSPF)
 - "Open" → open, non-proprietary standard, created under the auspices of the IETF
 - "SPF" → Shortest Path First, alternative name of link-state routing
- Implementation of Link-State Routing with added features
 - Authenticating of routing messages
 - Due to the fact too often some misconfigured hosts decide they can reach every host in the universe at a cost of 0
 - Additional hierarchy
 - Partition domain into areas → increase scalability
 - Load balancing
 - Allows multiple routes to the same place to be assigned the same cost → cause traffic to be distributed evenly over those routes

Open Shortest Path First

Protocol

OSPF Header Format Advertisement

OSPF Link State

	LS	Age	Options	Type=1		
Link-state ID						
Advertising router
