Outline

Public key infrastructure

D Certificate signature chains

- X.509 certification signature chains
- PGP certificate signature chains

Cryptographic Key Infrastructure

Goal: *bind identity to key*

- Classical cryptographic systems: not possible as all keys are shared
 - Two parties need to agree on a shared key (see earlier)
- Public key cryptographic systems: bind identity to public key
 - Crucial as people will use key to communicate with principal whose identity is bound to key
 - Erroneous binding means no secrecy between principals
 - Assume principal identified by an acceptable name

Binding Identity to Public Key

Bob wants to communicate with Alice

Alice must bind identity to her public key

D Main idea:

- Alice signs her public key (e_A) with her private key (d_A)
 - $\{e_A\}_{d_A}$
 - Not sufficient, because Bob would only know that whoever generated the public key also signed and cannot verify it is Alice who generated and signed the public key.
- Using a certificate (Kohnfelder, 1978)

Certificates

D Create token (message) containing

- Identity of principal (e.g., Alice)
- Corresponding public key (e.g., E_A)
- Timestamp (when the public key is issued, denoted as T)
- Other information (perhaps identity of signer)
- Signed by a trusted authority (e.g., Cathy), i.e., enciphered using Cathy's private key

 $C_A = \{ e_A \mid | Alice | | T \}_{d_C}$

□ C_A is a certificate, a token that binds an identity to a cryptographic key

9/2/2016

Using Certificate

Bob wants to communicate with Alice

Bob obtains Alice's certificate

 $C_A = \{ e_A \mid | Alice | | T \}_{d_C}$

- If he knows Cathy's public key, he can decipher the certificate
 - When was certificate issued?
 - □ Is the principal Alice?
- Now Bob has Alice's public key

Problem of Using Certificate

- Problem: Bob now needs issuer's, i.e., Cathy's public key to validate certificate
- The certificate approach pushes the problem "up" a level
 - Solution: construct a tree-like hierarchy
 - Using certificate signature chains
 - Using Merkle trees (Merkle, 1979): as further reading

Certificate Signature Chains

Issuer creates certificate

- Generate hash of certificate
- Encipher hash with issuer's private key
- Anyone can validate the certificate
 - Obtain issuer's public key
 - Decipher enciphered hash
 - Re-compute hash from certificate and compare
- □ Problem: how to obtain issuer's public key

Two Approaches

- Problem of Certificate Signature Chains: getting issuer's public key
- **D** Two approaches
 - To construct a tree-like hierarchy with the public key of the root known out of band
 - e.g., X.509 certificate signature chains
 - To allow an arbitrary arrangement of certifiers and rely on each individual's knowledge of the certifiers
 - e.g., PGP certificate signature chains

X.509 Certificate Signature Chains

□ ITU-T standard

D A public key infrastructure (PKI)

Certificate Authority (CA)

Entity that issues certificates

□ Multiple CAs exist in X.509

X.509 Certificate

□ Some certificate components in X.509v3 certificate:

- Version
- Serial number
- Signature algorithm identifier: hash algorithm
- Issuer's name: uniquely identifies issuer
- Interval of validity
- Subject's name: uniquely identifies subject
- Subject's public key
- Signature: enciphered hash

□ Issued and signed using a CA's private key

X.509 Certificate Validation

Obtain issuer's public key

- The one for the particular signature algorithm
- Decipher signature using the public key
 - Yields hash of certificate
- Re-compute hash from certificate and compare the two
 - If they differ, there is a problem
- **D** Check interval of validity
 - which confirms that certificate is current

Multiple Certificate Issuers

□ An example scenario

- Alice wants to communicate with Bob
 - Alice's local CA is Cathy and Alice has a certificate from Cathy
 - Bob's local CA is Dan and Bob has a certificate from Dan
- Validation problem caused by multiple CAs, i.e., certificate issuers
 - Alice and Bob need to validate each other's certificates
 - Alice's CA is Cathy; Bob's CA is Don; how can Alice validate Bob's certificate?
- Solution
 - Have Cathy and Don cross-certify
 - Each issuers issues certificate for the other issuer

Validation and Cross-Certifying

□ X<<Y>>: certificate that X generated for subject Y

Certificates

- Cathy<<Alice>>
- Dan<<Bob>
- Cathy<<Dan>>
- Dan<<Cathy>>
- □ Alice validates Bob's certificate
 - Alice obtains Cathy<<Dan>>
 - Alice uses (known) public key of Cathy to validate Cathy<<Dan>>
 - Alice uses Cathy<<Dan>> to validate Dan<<Bob>>

Cross-Verifying and Certificate Chain

- Cross-Verifying: Two CAs are cross-verified if each has issued a certificate for the other
- Signature Chain
 - Cathy is Alice's local CA and Alice has Cathy's public key. Alice can obtain certificate Cathy<<Dan>> and form the signature chain

Cathy<<Dan>>Dan<<Bob>

Similar argument can be made for Bob and Dan (Bob's CA)
 Dan<<Cathy>> Cathy<<Alice>>

Certificate Chain

- □ Signature chains can be of arbitrary length
- Each certificate can be validated by the one before it in the chain
- X.509 suggests organize CAs into a hierarchy to minimize the lengths of certificate signature chains
- Certificates can be revoked, or canceled
 - A list of such certificates enables a user to detect and reject invalidated certificates

PGP Certificate Signature Chains

D PGP: Pretty Good Privacy

- Widely used to provide privacy for e-mail through the Internet and to sign files digitally
- PGP uses a certificate-based key management infrastructure for users' public keys
- OpenPGP
 - http://openpgp.org

OpenPGP Certificate

- DpenPGP certificates are structured into packets
- □ Packet: a record with a tag describing its purpose
- A certificate consists of
 - One public key packet
 - Zero or more signature packets

OpenPGP Public Key Packet

□ Version

- 3 or 4
- 3 compatible with all versions of PGP
- 4 not compatible with older versions of PGP)

Creation time

- □ Validity period (not present in version 3)
- Public key algorithm, associated parameters
 Public key

OpenPGP Signature Packet

□ Version 3 signature packet

- Version (3)
- Signature type (level of trust)
- Creation time (when next fields hashed)
- Signer's key identifier (identifies key to encipher hash)
- Public key algorithm (used to encipher hash)
- Hash algorithm
- Part of signed hash (used for quick check)
- Signature (enciphered hash)

Version 4 packet more complex

Signing

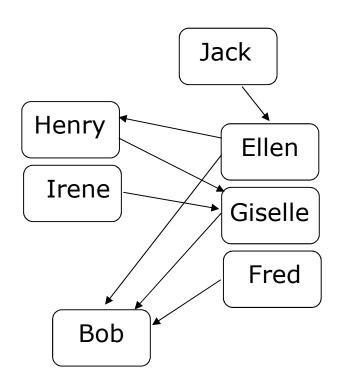

Single certificate may have multiple signatures

- Ellen,Fred,Giselle,Bob<<Bob>>
- Certificate that Ellen, Fred, Giselle, and Bob generated for Bob
 - The certificate is signed by Ellen, Fred, Giselle, and Bob
- D Notion of "trust" embedded in each signature
 - Range from "untrusted" to "ultimate trust"
 - Signer defines meaning of trust level (no standards!)
- All version 4 keys signed by subject
 - Called "self-signing"

Validating Certificates

- □ Scenario: Alice wants to communicate with Bob
- Alice obtains Bob's PGP certificate and needs to validate it
 - Ellen,Fred,Giselle,Bob<<Bob>>
 - Alice does not know Fred, Giselle, or Ellen
- □ Alice gets Giselle's PGP certificate
 - Henry, Irene, Giselle << Giselle >>
 - Alice knows Henry slightly
- □ Alice gets Henry's PGP certificate
 - Ellen,Henry<<Henry>>
 - Use it to verifies Giselle's certificate
 - But Henry's signature is at "casual" level of trust
- Alice gets Ellen's PGP certificate
 - Jack,Ellen<<Ellen>>
 - Knows Jack well, so uses his cert to validate Ellen's, then use Ellens to validate Bob's

- Arrows show signatures
- Self signatures not shown

Certificate Chains

In the above example, Alice followed two signature chains

- Henry<<Henry>>Henry<<Giselle>>Giselle<<Bob>>
- Jack<<Ellen>> Ellen<<Bob>>

Trust in X.509 and PGP

- X.509 certificates include an element of trust, but the trust is not indicated in the certificate
- PGP certificate indicate the level of trust, but the same level of trust may have different meanings to different signers

Summary

Public key infrastructure

Certificate signature chains

- X.509 certification signature chains
- PGP certificate signature chains
